

1 SPECIFICATION

2  
3 ACF TAPE FEEDER MACHINE, AND METHOD  
4 FOR FEEDING ACF TAPE  
5

6 BACKGROUND OF THE INVENTION

7 Field of the Art

8 This invention relates to an ACF (Anisotropic Conductive Film)  
9 tape feeder machine and a method for feeding ACF tape, suitable for  
10 use in feeding and bonding ACF on substrate plates, for example,  
11 suitable for use in a liquid crystal display panel fabrication process for  
12 bonding ACF on a transparent substrate plate of a liquid crystal cell for  
13 the purpose of mounting driver electronics thereon.

14 Prior Art

15 For example, driver electronics including a plural number of IC  
16 devices are connected to at least two side edges of a transparent  
17 substrate of a liquid crystal display panel. In some cases, the driver  
18 electronics are constituted by IC devices themselves. In some cases, IC  
19 devices are mounted on a film substrate to constitute driver electronics  
20 parts to be mounted on a transparent substrate or to be connected  
21 between a transparent substrate and a printed circuit board.

1           No matter which mounting method is employed, it is difficult to  
2 use solder in connecting electrodes on the side of the driver electronics  
3 parts to electrodes on the side of the substrate, which are formed in an  
4 extremely fine pitch. Therefore, ACF has been resorted to in the art in  
5 order to electrically connect the electrodes on the side of the driver  
6 electronics to the electrodes on the side of the substrate in a secure and  
7 reliable manner. ACF has conductive particles or grains dispersed in a  
8 binder resin with sticky and electrically insulating properties. After  
9 bonding AFC on a transparent substrate, driver electronics parts are  
10 bonded thereon by a TAB (Tape Automated Bonding) operation, and  
11 heat and pressure are applied thereto to electrically connect the  
12 electrodes on the side of the TAB-mounted electronics parts to the  
13 electrodes on the side of the transparent substrate through the  
14 conductive particles in ACF.

15           Generally, ACF is laminated to a predetermined thickness on one  
16 side of a liner tape through a releasing layer. The AFC tape is wound  
17 on a supply reel, and a fore end portion of the AFC tape is drawn out  
18 from the supply reel and bonded on a transparent substrate by the use  
19 of a bonding means.

20           The AFC tape which is wound on a supply reel is limited in  
21 length. Therefore, as soon as an AFC tape supply reel is consumed

1 completely, it has to be replaced by a fresh supply reel. At an AFC tape  
2 feeding station, a supply reel is set on a reel support shaft, and, when  
3 consumed completely, dismantled therefrom and replaced by a fresh  
4 supply reel. The reel replacing job is not completed simply by setting a  
5 fresh supply reel on the reel support shaft. It also involves a job of  
6 drawing out a fore end portion of the AFC tape on the newly set supply  
7 reel and connecting same to a bonding means. Namely, actually the  
8 reel replacement job involves a tape end connecting job in addition to  
9 reel replacement.

10 Heretofore, the reel replacing and tape end connecting jobs have  
11 relied on manual labor of an operator despite the fact that these jobs  
12 are troublesome and time consuming. Especially, since the ACF tape  
13 has an adhesive surface on one side, an operator is required to pay  
14 great attention not to touch the adhesive surface. Namely, the operator  
15 has to handle the ACF tape very carefully in reeling off a fore end  
16 portion of the ACF tape from a fresh supply reel and connecting same  
17 to a bonding means even if it takes a relatively long period of time.

18 Of course, the operation of mounting driver electronics parts on a  
19 substrate is suspended during the reel replacement and the tape end  
20 connecting operation, resulting in great time losses. Besides, in order  
21 to minimize the time losses, the operator needs to watch the progress of

1 a tape feeding operation and to replace a supply reel by a fresh one in a  
2 good timing, that is to say, as soon as the tape from one reel is  
3 completely consumed. Accordingly, the operator has to stand by  
4 exclusively for this purpose from well before a time point when tape  
5 supply from a currently operating supply reel comes to an end. As a  
6 result, the operational efficiency is deteriorated considerably by the reel  
7 replacements because the operator cannot do other jobs during each  
8 standby period.

9 Especially, as a result of recent progresses and improvements in  
10 automatic mounting apparatus for electronic circuitry parts, there has  
11 been a trend toward speeding up the tact time of electronic parts  
12 mounting operations, consuming the ACF tape of each supply reel in a  
13 shortened period of time and as a result necessitating to replace the  
14 supply reel at a higher frequency. It is a paramount requisite to  
15 shorten the time period of the reel replacements in order to shorten a  
16 time period for mounting each electronic part.

#### 17 SUMMARY OF THE INVENTION

18 In view of the foregoing situations, it is an object of the present  
19 invention to make it possible to replace an empty ACF tape supply reel  
20 by a fresh reel and to connect a fore end portion of an ACF tape from  
21 the fresh supply reel to a bonding means of an ACF tape feeder

1 machine quickly and smoothly, permitting to set a fresh supply reel in  
2 a standby position at any time or in an arbitrary timing, irrespective of  
3 the progress of a current tape feeding operation.

4 It is another object of the present invention to make it possible to  
5 carry out a reel replacing job and a tape end connecting job separately  
6 in different timings, permitting to carry out a reel replacing job  
7 concurrently or in overlapped relation with an ACF tape feeding  
8 operation from other supply reel.

9 It is still another object of the present invention to make it  
10 possible to shorten the time for reel replacements and to permit an  
11 uninterrupted ACF tape feeding operation by the use of ACF tape  
12 supply reels each loaded with a limited length of ACF tape.

13 In accordance with the present invention, in order to achieve the  
14 above-stated objectives, there is provided an ACF (Anisotropic  
15 Conductive Film) tape feeder machine having an ACF bonding means  
16 adapted to draw out an ACF tape, with an ACF laminated on a liner  
17 tape, from a supply reel set in a feed position at an ACF tape feeding  
18 station, and to bond the ACF on substrate plate surfaces one after  
19 another over a predetermined length, characterized in that: the ACF  
20 tape feeding station is provided with a reel stand having at least two  
21 reel mount members for setting at least two ACF tape supply reels

1 separately thereon; the reel mount members of the reel stand are  
2 connected to a switch means and switchable to and from an operating  
3 position for reeling out the ACF tape to the bonding means and a  
4 standby position.

5 Further, according to the present invention, there is also provided  
6 a method for feeding an ACF tape, comprising the steps of; providing at  
7 least two reel support members on a reel stand to support and set at  
8 least two ACF tape supply reels thereon, one in an operating position  
9 for reeling off an ACF tape and the other one in a standby position;  
10 while an ACF tape from a supply reel in the operating position is being  
11 bonded on substrate plates by the use of a bonding means, replacing  
12 an empty supply reel in the standby position by a fresh ACF tape  
13 supply reel; as soon as the ACF tape supply reel in the operating  
14 position becomes empty, switching positions of the reel mount  
15 members to locate the reel mount member with the fresh ACF tape  
16 supply reel in the operating position; and drawing out an ACF tape  
17 from the fresh reel and connecting the same to said bonding means.

18 In this instance, the tape supply reels are set on reel mount  
19 members which are provided on a reel stand. Each one of the reel  
20 mount members is provided with at least one reel support shaft.  
21 Further, in order to make an automatic tape end connecting operation

feasible, a tape end holder member is provided on each reel mount member thereby to grip a fore end of an ACF tape which is reeled off from a supply reel over a predetermined length. Alternatively, the tape end holder member may be arranged into the so-called cassette type which is provided integrally with the tape supply reel. In a case where a tape supply reel is mounted directly on a reel support shaft, the tape end holder member is provided on each one of the reel mount members of the reel stand. Otherwise, an adhesive medium may be used for holding a fore end portion of an ACF tape on the reel mount member. It is also possible to employ a chuck means for this purpose.

Furthermore, the end holder member can be arranged to grip the liner tape by smoothly. In this regard, it is preferable to employ a suction type end holder member because it is simple in construction and capable of holding and releasing a tape by smooth actions. A fore end portion of the ACF tape, which is gripped by the tape end holder member, has to be handed over to the bonding means. In a case where the tape end holder member is constituted by a mechanical chuck means, the handover can be made directly. However, it is also possible to provide a tape handover means which is arranged in such a way as to pick up an ACF tape from the tape end holder member on the tape supplying side and then hand over the tape to the bonding means.

1           As for the bonding means, it is possible to employ various  
2 mechanisms and systems which have been known in the art. For  
3 example, the bonding means can be largely constituted by a chuck  
4 member which is adapted to grip a fore end portion of ACF tape, a  
5 bonding roller adapted to press an ACF tape from above to bond an  
6 ACF side of the tape against a substrate plate. In this case, the  
7 bonding means is movable on and along a substrate plate. The liner  
8 tape of the AFC tape has to be peeled off after bonding the AFC on a  
9 substrate plate. Therefore, it is desirable to provide a peeler roller on  
10 the bonding means. In a case where the bonding means is provided  
11 with a chuck member for gripping a fore end portion of ACF tape, the  
12 tape handover means should preferably include a handover chuck  
13 member which is adapted to pick up an ACF tape from the tape end  
14 holder member and then hand it over to the chuck member of the  
15 bonding means.

16           The reel stand which supports the two reel mount members is  
17 connected to a switch means thereby to switch the reel mount members  
18 to and from an operating or tape supply position and a standby  
19 position. Therefore, each reel mount member is provided with a reel  
20 support shaft and a tape end holder member thereon. The two reel  
21 mount members are switched alternately from the operating to standby

1 position and from the standby to operating position in an interlinked  
2 manner. In switching the positions of the reel mount members, they  
3 may be displaced in vertical or lateral directions. However, in order to  
4 replace supply reels constantly at the same position, it is preferred to  
5 couple the reel stand with a rotational shaft and to turn one of the reel  
6 mount members on the reel stand selectively into the operating position  
7 by turning the rotational shaft back and forth through a predetermined  
8 angle, for example, through 180 degrees. One supply reel is set in the  
9 operating or tape feeding position, while one or a plural number of  
10 supply reels may be set in a standby position or positions. For  
11 example, four reel mount members may be provided on an indexing  
12 rotational shaft with a positional phase difference of 90 degrees from  
13 each other. In this case, the supply reels on the four reel mount  
14 members are successively advanced into an operating position by an  
15 indexing rotation as soon as a supply reel in a preceding position is  
16 consumed completely, that is to say, three supply reels are held in  
17 standby positions while one supply reel is in the tape supplying  
18 operation.

19 The above and other objects, features and advantages of the  
20 present invention will become apparent from the follow particular  
21 description, taken in conjunction with the accompanying drawings

1 which show by way of example some preferred embodiments of the  
2 invention. Needless to say, the present invention is not limited to the  
3 particular forms which are shown in the accompanying drawings for  
4 illustrative purposes.

#### 5 BRIEF DESCRIPTION OF THE DRAWINGS

6 Fig. 1 is a fragmentary outer view of a liquid crystal display  
7 panel, shown as an example of application of an AFC feeder (bonding)  
8 machine according to the present invention;

9 Fig. 2 is a schematic sectional view of a TAB mount portion of a  
10 liquid crystal display panel;

11 Fig. 3 is a schematic sectional view of an ACF tape;

12 Fig. 4 is a schematic illustration of an ACF bonding machine  
13 according to the present invention;

14 Fig. 5 is a perspective view of a bonding unit and a peeling chuck;

15 Fig. 6 is a schematic front view of a reel stand;

16 Fig. 7 is a schematic plan view of the reel stand in an operational  
17 phase of replacing a supply reel in a standby position;

18 Fig. 8 is a schematic illustration of a tape handover means;

19 Fig. 9 is a schematic side view of the tape handover means of Fig.  
20 8;

21 Fig. 10 is a schematic illustration explanatory of a first step of an

1 ACF tape end connecting operation;

2 Fig. 11 is a schematic illustration explanatory of a second step of  
3 the ACF tape end connecting operation;

4 Fig. 12 is a schematic illustration explanatory of a third step of  
5 the ACF tape end connecting operation;

6 Fig. 13 is a schematic illustration explanatory of a fourth step of  
7 the ACF tape end connecting operation; and

8 Fig. 14 is a schematic illustration explanatory of a fifth step of  
9 the ACF tape end connecting operation.

#### 10 DESCRIPTION OF PREFERRED EMBODIMENTS

11 Hereafter, the present invention is described more particularly by  
12 way of its preferred embodiment shown in the accompanying drawings.  
13 Firstly, reference is had to the outer view of a liquid crystal cell in Fig.  
14 1, the sectional view of a TAB mount portion in Fig. 2, and the sectional  
15 view of ACF tape in Fig. 3.

16 In Fig. 1, the liquid crystal cell 1 has liquid crystal sealed in a cell  
17 gap which is formed between two overlapped transparent substrate  
18 plates, for example, between two substrate plates of glass. Here, the  
19 two substrate plates 2 and 3 which constitute the liquid crystal cell 1  
20 are referred to as a lower substrate 2 and an upper substrate 3,  
21 respectively. Electrode patterns are formed on confronting inner

1 surfaces of the lower and upper substrate plates 2 and 3 by printing or  
2 other suitable means, in groups each consisting of a plural number of  
3 electrodes as indicated by reference numeral 4. In the case of the lower  
4 substrate plate 2, for instance, groups of electrodes 4 are formed along  
5 at least two sides thereof. Each electrode group 4 of the lower  
6 substrate plate 2 is electrically connected to a group of electrodes 7 on  
7 the side of a driver electronics part 9 having an IC device 6 mounted on  
8 a wiring board film 5 and having electrode groups 7 and 8 of a  
9 predetermined number formed on the opposite sides of the IC device 6.

10 An ACF tape 10 is used for mounting the driver electronics part 9  
11 on the lower substrate plate 2 with the electrode group 7 on the side of  
12 the driver in an electrically connected state the electrode group 4 on the  
13 side of the substrate plate. As seen in Figs. 2 and 3, ACF has  
14 conductive particles 10b uniformly dispersed in a binder resin material  
15 10a with sticky and electrically insulating properties. The conductive  
16 particles are smaller in size than the intervals between individual  
17 electrodes in the electrode group 7 on the side of the driver and in the  
18 electrode group 4 on the side of the substrate plate. The ACF is  
19 interposed between the lower substrate plate 2 and the driver  
20 electronics part 9, and, after softening the binder resin 10a, pressure is  
21 applied to the lower substrate 2 and the driver electronics part 9,

1 reducing the thickness of the ACF 10 almost to the grain size of the  
2 conductive particles 10b and thereby bringing the conductive particles  
3 into contact with electrodes 4a and 7a of the electrode group 4 on the  
4 side of the substrate plate and the electrode group 7 on the side of the  
5 driver to establish electrical connections therebetween. Upon  
6 hardening the binder resin 10a, the driver electronics part 9 is securely  
7 fixed to the lower substrate plate 2.

8 As clear from Fig. 3, ACF10 is laminated on a liner tape 11 and  
9 provided in the form of an ACF tape 12. The laminated layer of ACF 10  
10 is releasable from the liner tape 11. Therefore, the liner tape 11 can be  
11 peeled off when the ACF 10 is bonded on and fixed to the lower  
12 substrate plate 2. As a result, the ACF layer 10 of the ACF tape 12 is  
13 bonded on the lower substrate plate 2.

14 As shown in Fig. 4, the ACF tape 12 is wound on a supply reel  
15 13, and reeled off therefrom and bonded on the lower substrate plate 2.  
16 The liquid crystal cell 1 is mounted on a carriage table 14 with a  
17 positioning mechanism, and delivered to an ACF bonding station 15.  
18 Guide rollers 16 are provided at suitable positions along a tape supply  
19 route to be taken by the ACF tape 12 from the supply reel 13. These  
20 guide rollers 16 are held in engagement with the ACF tape 12 on the  
21 side of the liner tape 11.

1            Provided in the course of a tape supply route, taken by an ACF  
2       tape which has been drawn out by the guide rollers 16, is a half cutter  
3       means 17 which serves to remove the ACF 10 over a predetermined  
4       length and at predetermined intervals.

5            Further, in Fig. 4, shown at 18 is a bonding means and at 19 a  
6       collecting means. The bonding means 18 is composed of a roller  
7       assembly unit including a bonding roller 20, guide rollers 21 and 22  
8       which are located on the upstream and downstream sides of the  
9       bonding roller 20 and a peeling roller 23, and a drawing chuck member  
10      24. All of just-members are mounted on a carriage block 25. As seen  
11      in Fig. 5, the carriage block 25 is moved back and forth by a horizontal  
12      transfer unit, including a guide rail 26a and a drive means 26b, to  
13      reciprocate to and from predetermined initial and end positions. The  
14      carriage block 25 can be stopped at any aimed position in the course of  
15      its horizontal stroke. The collecting means 19 is provided for collecting  
16      the liner tape 11 which is peeled off the ACF 10 after bonding the latter  
17      on the lower substrate plate 2, and composed of a peeling chuck  
18      member 27 and a collecting box 28. The collecting box 28 is adapted to  
19      collect the peeled liner tape 11 by suction force.

20           The bonding roller 20 and the guide rollers 21 and 22 of the  
21      bonding means 18 mounted on a lift means 29 and thereby moved to

1 and from a lower position at which the ACF tape is brought into  
2 abutting engagement with the lower substrate plate 2 and an upper  
3 receded position away from the lower substrate plate 2. The peeler  
4 roller 23 which is located downstream of the bonding roller 20 in the  
5 travel direction of the ACF tape 12 is fixedly retained in position in the  
6 vertical direction. Opened between the guide roller 22 and the peeler  
7 roller 23 is a gap space to permit passage of a handover chuck member  
8 46 which will be described hereinlater.

9 The ACF bonding machine is generally arranged as described  
10 above. The carriage block 25 is located at an initial position in the  
11 proximity of the supply reel 13. At the initial position, the ACF tape 12  
12 is gripped by the drawing chuck member 13, and, while the ACF tape  
13 12 is being gripped by the drawing chuck member 24, a bonding  
14 operation is started from this position to bond ACF 10 on the lower  
15 substrate plate 2 of the liquid crystal cell 1. In this instance, by the  
16 half cut means 17, ACF 10 has been peeled off from the chuck portion  
17 of the ACF tape 12 to be gripped by the drawing chuck member 24.  
18 Thus, it is the liner tape 11 that is actually gripped by the drawing  
19 chuck member 24, and there is no possibility of the drawing chuck  
20 member 24 coming into direct contact with ACF 10.

21 The carriage block 25 is moved forward to a bonding start

1 position where the bonding roller 20 starts to bond ACF 10 on the lower  
2 substrate 2 of the liquid crystal cell 1. Then, the lift means 29 is  
3 actuated to lower the bonding roller 20 and the front and rear guide  
4 rollers 21 and 22 until the ACF tape 12 is abutted on the lower  
5 substrate plate 2. At this time, normally the carriage block 25 is  
6 temporarily held at rest. However, if desired, the lift means may be  
7 actuated during movement of the carriage block 25. The carriage block  
8 25 is then put in travel, letting the bonding roller 20 and the front and  
9 rear guide rollers 21 and 22 along the surface of the lower substrate  
10 plate 2. At this time, by the bonding roller 20, ACF 10 of the ACF tape  
11 12 is bonded on the lower substrate plate 2 under a predetermined  
12 pressure.

13 As soon as the bonding roller 20 is displaced to an end position of  
14 the ACF bonding operation on the lower substrate 2, the carriage block  
15 25 is stopped. Then, the peeling chuck member 27 is actuated to grip  
16 the ACF tape 12. Since the ACF 10 had already been peeled off at a  
17 position forward of the bonding means 18, at this time it is the liner  
18 tape 11 that is gripped by the peeling chuck member 27. After this, the  
19 drawing chuck member 24 is opened to release the ACF tape 12. In  
20 this state, the carriage block 25 is moved toward the initial position.  
21 The peeler roller 23 is engaged with that side of the liner tape 11 where

1 a releasing layer is formed, and located in a spaced position from the  
2 lower substrate plate 2. Therefore, the liner tape 11 is peeled off ACF  
3 10 which has been bonded to the lower substrate plate 2. As soon as  
4 ACF 10 is completely separated from the liner tape 11, the bonding  
5 roller 20 and the guide rollers 21 and 22 are lifted up by the lift means  
6 29, and then the drawing chuck member 24 is closed to grip the liner  
7 tape 11 which has been separated from the bonded ACF 10, and at the  
8 same time the peeling chuck member 27 is opened to release the tape.

9 After the above operation, the machine becomes ready for  
10 starting an ACF bonding operation on a next liquid crystal cell 1.  
11 Therefore, as soon as a fresh liquid crystal cell 1 is delivered on the  
12 transfer table 14, the machine is operated to repeat the above-described  
13 operation. As the carriage block 25 is moved to reel off the ACF tape 12  
14 and the ACF 10 is bonded by the bonding roller 20, the peeled and  
15 used portion of the liner tape 11 is fed forward and collected into the  
16 collecting box 28 by suction force.

17 As the ACF bonding operation is repeated continuously, sooner or  
18 later the ACF tape 12 on the supply reel 13 is totally consumed. In  
19 order to continue the bonding operation, the consumed supply reel has  
20 to be removed and replaced by a fresh supply reel. At time time, after  
21 setting a fresh supply reel in position at the tape feeding station, it

1 becomes necessary to draw out a fore end of an ACF tape 12 from the  
2 fresh reel as far as the bonding means 18 and to chuck it on the  
3 drawing chuck member 24. According to the present invention, the reel  
4 replacing and the tape end connecting operations can be completed  
5 very smoothly. By nature, the reel replacement and the tape end  
6 connection are different jobs. Namely, what is involved are a job of  
7 replacing a consumed reel by a fresh reel, and a job of drawing a fore  
8 end of an ACF tape 12 from the fresh reel and getting the fore tape end  
9 chucked on the drawing chuck member 24 of the bonding mechanism  
10 18. Therefore, the jobs for the reel replacement and the tape end  
11 chucking are performed in different timings and by the use of different  
12 means.

13         The fore end of the ACF tape can be connected either by drawing  
14 out the fore end of the ACF tape 12 from the supply reel 13 until it  
15 reaches the drawing chuck member 24 of the bonding mechanism or  
16 by drawing out a fore end of the ACF tape 12 of the reel 13 to a  
17 predetermined position and then moving the drawing chuck member 24  
18 toward that position to grip the fore end of the ACF tape 12. This tape  
19 connecting operation can be performed automatically. Besides, by  
20 nature, the tape connecting operation cannot be carried out until a  
21 currently used supply reel is completely consumed to an empty state,

1 that is to say, the tape connecting operation has to be carried out in a  
2 timing which is restricted by operating conditions of the ACF bonding  
3 machine.

4 On the other hand, automation of the reel replacements is also  
5 possible but for this purpose it becomes necessary to install a robot or  
6 the like for automatically performing the jobs removing an empty reel  
7 and setting a fresh supply reel in position, in addition to the necessity  
8 for providing a place for stocking fresh reels. Therefore, an automatic  
9 ACF bonding machine necessarily becomes complicated in construction  
10 and larger in scale. Further, the robot is required to perform  
11 operations which involve extremely complicate actions. Therefore, it is  
12 more rational to replace tape supply reels manually by an operator.  
13 Besides, if a fresh supply reel can be held in a standby position, it  
14 becomes possible to replace tape supply reels at any time and in a  
15 desired timing, irrespective of operating conditions of the ACF bonding  
16 machine.

17 In order to permit replacements of tape supply reels in a more  
18 casual or arbitrary timing, a supply reel stand 30 is arranged to  
19 support a couple of supply reels 13 thereon as shown in Figs. 6 and 7.  
20 The supply reel stand 30 is largely constituted by an upright reel mount  
21 member 31, reel support shafts 32 provided on the opposite sides of the

1 reel mount member 31 and adapted to support a tape supply reel 13  
2 thereon, and guide rollers 33 (corresponding to guide rollers 16 in Fig.  
3 4) provided on each side of the reel mount member 31 to guide an ACF  
4 tape which is reeled off from the tape supply reel 13. Further, a tape  
5 end holder member 34 is provided substantially at a foremost position  
6 in a tape travel path which is formed on the reel mount member 31 by  
7 the guide rollers 33. In this instance, the tape end holder member 34 is  
8 provided with a suction hole 35 on the lower side thereof to grip a front  
9 side of a liner tape 11 by suction force.

10 As shown in Fig. 7, a pair of reel mount members 31 are  
11 supported on a reversing shaft 36 with 180 degrees phase difference  
12 from each other. Each one of these reel mount members 31 is securely  
13 fixed to the reversing shaft 36 on the back side, that is to say, on the  
14 side away from the front side on which the tape supply reel 13 is  
15 supported. This reversing shaft 36 is rotated back and forth through  
16 180 degrees by a drive means which is not shown.

17 In the case of the particular embodiment shown in Fig. 7, the side  
18 labeled with "S" is a supply side which is being by a reel 13 currently in  
19 operation for supplying the ACF tape 12, and the side labeled with "W"  
20 is a side being used by a fresh supply reel which is held in a standby  
21 state until the ACF tape 12 of the tape supply reel 13 on the other side

1 "S" is completely consumed. Namely, in Fig. 7, a letter "S" or "W" is  
2 affixed to the reference numerals to distinguish the reel mount member  
3 and the tape supply reel on the supply side "S" from the counterparts  
4 on the standby side "W". Further, the standby side "W" which is used  
5 for reel replacements is now in the process of reel replacement in Fig. 7.

6 A consumed reel is replaced by a fresh reel in the manner as  
7 described below. For this purpose, a reel replacing operation is started  
8 with removal of a stopper 32a which is detachably fixed on the reel  
9 support shaft 32 on the side of the reel mount member 31W, as shown  
10 in Fig. 7. Then, an empty reel is removed, and a fresh reel 13W is set in  
11 position on the reel support shaft 32 and locked in that position by  
12 attaching the stopper 32a again to the reel support shaft 32. Before or  
13 at this stage of replacement, the ACF 10 is peeled off the fore distal end  
14 of the ACF tape 12 from the reel 13W over a predetermined length.  
15 Thereafter, the AFC tape 12 is reeled off from the supply reel 13W along  
16 the tape travel path around the guide rollers 33 on the reel mount  
17 member 31 until the fore end of the tape is sucked and gripped by the  
18 suction hole 35 of the tape end holder member 34.

19 One cycle of reel replacing operation is completed by the above  
20 described operations. Even during this reel replacing operation, the  
21 supply of the ACF tape 12 from the tape supply reel 13 on the reel

1 mount member 31S on the currently supplying side "S" is continued  
2 without influenced by the reel replacement. Namely, the reel  
3 replacement can be carried out at any time point during a time period  
4 between start and end of the supply of the ACF tape 12 from the supply  
5 reel 13 on the side of the reel mount member 31S. Accordingly, an  
6 operator can replace reels at any time and in an arbitrary timing. This  
7 means that the operator is no longer required to waste time for standing  
8 by and waiting for appropriate timings of reel replacements. In  
9 addition, supply reels can be replaced quickly in a facilitated manner,  
10 contributing to enhance the working efficiency of the operator all the  
11 more.

12 The supply of the ACF tape 12 from the tape supplying side "S" is  
13 continued even after the supply reel 13W is set in position on the reel  
14 mount member 31W on the standby side "W". As soon as all of the ACF  
15 tape 12 on the reel 13S on the reel mount member 31S on the tape  
16 supplying side "S" is used up and collected in the collection box 28, this  
17 is detected by a sensor (not shown), and, in response to a signal from  
18 the sensor, the reversing shaft 36 is turned around to reverse the  
19 positions of the reel mount members on the tape supplying side "S" and  
20 the standby side "W", turning the tape supply reel 13S on the reel  
21 mount member 31S into the position on the standby side "W" while

1 turning the tape supply reel 13W on the reel mount member 31W into  
2 the position on the tape supplying side "S". Accordingly, after the  
3 reversal of reel positions, the reel mount member 31S operates as the  
4 reel mount member 31W on the standby side "W" while the reel mount  
5 member 31W operates as the reel mount member 31S on the supplying  
6 side "S". However, in this state, it is not yet possible to supply the ACF  
7 tape 12 from the supply reel 13S which has been turned into the tape  
8 supplying side "S". The fore end of the ACF tape 12 has to be  
9 connected to the drawing chuck member by a tape end connecting  
10 operation. In order to perform this tape end connecting operation  
11 automatically, the bonding machine is provided with a tape handover  
12 means 40 as shown in Figs. 8 and 9.

13 The tape handover means 40 is provided with a support member  
14 41 which is located fixedly at a position which will not interfere with  
15 reversing actions of the reel stand 30, travel path of the ACF tape 12  
16 which is fed out from the supply reel 13, and operational actions of the  
17 bonding means 18. Mounted on the support member 41 are a lift drive  
18 cylinder 42, a couple of slide guides 43, and a couple of support rods 44  
19 which are driven up and down by the cylinder 42 and respectively  
20 guided by the slide guides 43. An actuator 45 is attached to the lower  
21 ends of the support rods 44 thereby to open and close a handover

1 chuck member 46.

2           Thus, as the handover chuck member 46 is closed by the  
3 actuator 45, the ACF tape 12 is gripped between the upper and lower  
4 chuck portions 46a as indicated by solid line in Fig. 9. On the contrary,  
5 when the handover chuck member 46 is opened, the upper and lower  
6 chuck portions 46a are swung open in the upward and downward  
7 directions, respectively, as indicated in phantom in Fig. 9 to take  
8 receded positions away from the travel path of the ACF tape 12. The  
9 support rods 44, which support the assembly of the handover chuck  
10 member and the actuator 45, is movable at least to and from an upper  
11 lifted position, a lowered position and at least one intermediate position.

12           By operation of the tape handover means 40 with the above-  
13 described arrangements, the fore end of the ACF tape 12 which is  
14 gripped by the tape end holder member 34 can be drawn out from the  
15 supply reel 13 and handed over to the drawing chuck member 24 of the  
16 bonding means 18. In this instance, the ACF tape 12 is passed on the  
17 lower side of the bonding roller 20 and the front and rear guide rollers  
18 21 and 22 and on the upper side of the peeler roller 23, and gripped in  
19 the drawing chuck member 24. Namely, by operation of the tape  
20 handover means 40, the fore end of the ACF tape 12 is routed under  
21 and over the respective rollers in the manner just described, and

1 handed over to the drawing chuck member 24 automatically without  
2 relying on manual labor.

3 Now, the handover operation is explained with reference to Figs.  
4 10 through 14. In the first place, the handover chuck member 46 of the  
5 tape handover means 40, which is in an opened state, is located in a  
6 position at the same height with the ACF tape 12 which is sucked on  
7 the tape end holder member 34 on the reel stand 30. Then, the  
8 reversing shaft 36 is rotated through 180 degrees to reverse the  
9 positions of the two reel mount members, and, the handover chuck  
10 member 46 is actuated to grip the fore end of the ACF tape 12 which  
11 has been sucked on the tape end holder member 34 on the reel mount  
12 member 31S of the tape supplying side "S". At this time, the liner tape  
13 11 alone is gripped by the handover chuck member 46 because the ACF  
14 10 has already been peeled off from that portion of the ACF tape 12.  
15 The suction grip of the tape end holder member 34 is then turned off to  
16 release the ACF tape 12.

17 As soon as the ACF tape 12 is gripped and fetched by the  
18 handover chuck member 46, the cylinder 42 is actuated to lower the  
19 handover chuck member 46. At a lowered position, the ACF tape 12 is  
20 located at a level lower than the bonding roller 20 and the front and  
21 rear guide rollers 21 and 22 of the bonding means 18, as seen

1 particularly in Fig. 10. From the position shown in Fig. 10, the carriage  
2 block 25 of the bonding means 18 is moved in the leftward direction in  
3 that figure, that is to say, in the backward direction relative to the  
4 travel direction of the ACF tape 12 to bring the handover chuck member  
5 46 to a position between the guide roller 22 and the peeler roller 23, as  
6 shown particularly in Fig. 11.

7 The handover chuck member 46, in the position of Fig. 11, is  
8 then moved upward into an upper lifted position whereupon the ACF  
9 tape 12 is oriented to run along the lower side of the bonding roller 20  
10 and the front and rear guide rollers 21 and 22 and then rise to a level  
11 over the peeler roller 23 as shown particularly in Fig. 12. Thereafter,  
12 the carriage block 25 is moved further in the leftward direction,  
13 displacing the peeler roller 23 forward past the position of the handover  
14 chuck member 46 and relocating the drawing chuck member 24 at a  
15 position forward of the handover chuck member 46. At this time, the  
16 drawing chuck member 24 of the bonding means 18 is retained in an  
17 opened state, and the handover chuck member 46 is lowered to a  
18 position at an intermediate level between the upper and lower chuck  
19 portions of the drawing chuck member 24. In this state, the carriage  
20 block 25 is moved further in the leftward direction, whereupon the  
21 handover chuck member 46 is passed through the drawing chuck

1 member 24 as shown particularly in Fig. 13.

2 Then, as shown in Fig. 14, the drawing chuck member 24 is  
3 closed to grip the ACF tape 12, and succeeding the handover chuck  
4 member 46 is opened to release the ACF tape 12. As a consequence,  
5 the fore end of the ACF tape 12 from the supply reel 13S is now gripped  
6 by the drawing chuck member 24, that is to say, the ACF tape from the  
7 supply reel 13S is now connected to the bonding means 18. Thus, the  
8 machine is ready to start the operation of bonding the ACF 10 on a  
9 lower substrate of a liquid crystal cell.

10 As described above, the replacement of the supply reel 13, which  
11 is necessary for the ACF bonding machine to continue the AFC bonding  
12 operation continuously in an uninterrupted manner, can be carried out  
13 in an arbitrary timing which is convenient to the operator, and a fore  
14 end of an ACF tape from a fresh supply reel is connected to the bonding  
15 means 18 automatically without requiring manual labor of an operator  
16 as soon as an ACF tape from a currently operating supply reel is  
17 completely consumed. The combination of the manual reel replacement  
18 and the automatic tape connecting operation makes it possible to carry  
19 out required jobs speedily and efficiently, suppressing time losses to a  
20 minimum. It becomes unnecessary for the operator to stand by and  
21 wait for reel replacement. Accordingly, in automatically mounting

1 driver electronics parts on liquid crystal cells 1, the operation can be  
2 carried out at an accelerated tact time, let alone improvements in  
3 working efficiency of the operator who is required to attend to various  
4 jobs.
